Abstract. Complex problem solving requires diverse expertise and multiple techniques. In order to solve such problems, complex multi-agent systems are needed, which may include both of human experts and autonomous agents, to work together in many areas. Most complex multi-agent systems are working in open domains. Due to heterogeneities and dynamic working environments, expertise and capabilities of agents might not be well estimated and presented in these systems. Therefore, how to discover useful knowledge from human and autonomous experts, make more accurate estimation for experts' capabilities and find out suitable expert(s) to solve incoming problems ("Expert Mining") are important research issues in the area of multi-agent system. In this paper, we introduce an ontology-based approach for knowledge and expert mining in hybrid multi-agent systems. In this research, ontologies are hired to describe knowledge of the system. Knowledge and expert mining processes are executed as the system handle incoming problems. In this approach, we embed more self-learning and self-adjusting abilities in multi-agent systems, and make it easier to discover knowledge of heterogeneous experts of multi-agent systems.

Keywords: *knowledge discovery, knowledge mining, expert mining, multi-agent system*

1 Introduction

Nowadays, many complex problems require diverse expertise and multiple techniques. In order to solve such problems, numbers of heterogeneous agents [16, 17], which may include both of human experts and autonomous agents, are sometimes required to work together in some open domains [1, 12]. In these complex domains, agents' number, experiences and expertise may not be stable. Also, due to heterogeneities, expertise and capabilities of agents might not be well estimated by the system. In this case, how to discover useful knowledge from human and autonomous experts, make more

accurate estimation for experts' capabilities and find out suitable expert(s) to solve incoming problems is an important research issue in multiple areas, which include multi-agent systems, distributed information retrieval, distributed problem solving, data-mining, etc.

For complex multi-agent systems, cooperative problem solving can normally be achieved through the following three major approaches: (1) cooperation protocols [16], (2) coordination mechanisms [5], and (3) communication language or protocols [8, 15]. Most cooperation and coordination protocols or mechanisms are managed by centralized control. When an agent world becomes more complex and dynamic, centralized approaches show the strong weakness in effective coordination among agent systems. Traditional communication languages are message-based communication and have been adopted by many MAS applications and agent platforms, such as JACK [6], ZEUS [18] and FIPA-OS [7]. However, the message-based ACL also have some weaknesses. Agents that use the message-based ACL to communicate with each other must fully understand all vocabularies of the language. This shortcoming restricts agents to limited vocabularies, and increases the risk of the communication. In order to overcome the limitations of message-based communication, some researchers in MASs proposed on the knowledge-based communication. Generally, knowledge-based communication languages enable agents to express properties of objects and relationships between objects within their information. One typical knowledge-based ACL is the Knowledge Interchange Format (KIF) [10]. Knowledge-based communication languages are widely applied in web-based applications. However, most knowledge-based communication languages were not originally developed for agent applications in open environments. Therefore many agent actions cannot be described in these languages. This feature greatly restricts the use of these languages.

In order to overcome some limitations mentioned above, we have proposed different decentralized approaches for complexity of problem solving through different methodologies, such as dynamic team forming strategies [3], colored Petri Net approach [4] for modeling of interactions among heterogeneous agents in both self-interested agent systems and cooperative agent systems. These approaches are designed for traditional multi-agent systems but might not work properly for complex multi-agent systems in which external knowledge sources of a MAS could be developed by different organisations for different purposes. These knowledge sources update their data independently, and may use different formats to represent knowledge. To work together in the same MAS to achieve some common goals, these heterogene-

ous agents need to interact with each other to exchange their knowledge or acquire domain knowledge from the system. The motivation of this research is to help agents obtain the latest domain knowledge from various knowledge sources through knowledge management mechanisms in MASs to form a knowledge level communication and interaction for complex problem solving in open domains.

In this paper, we introduce an ontology-based approach for knowledge and expert mining [13], which is to discover specialized knowledge and expertise of experts, in hybrid multi-agent systems. In this approach, ontologies are used to describe knowledge of the system. The knowledge and expert mining, which is a life-time long process, will be performed through update the ontology of the system. The knowledge and expert mining are processed as the experts of the system solve incoming problems.

The rest of the paper is organized as follows. In Section 2, we present some basic concepts of multi-agent systems (MASs) and complex multi-agent systems (CMASs). In Section 3, the concept of ontology and ontology of the CMAS is introduced. We propose the ontology-based approach in Section 4. Finally, the conclusion is given in Section 5.

2　Experts and Knowledge in Complex Multi-agent Systems

Knowledge discovery is a preliminary and an important process for multi-agent system (MAS) applications. It mainly contains two processes:

1. Initial understanding the problem domain and describing incoming problems in an agent-readable format;
2. Understanding agents' capabilities and expertises.

Knowledge discovery for MASs with heterogenous agents is more difficult then common MASs. Here, we define a MAS with hybrid agents (human and autonomous agents) as a complex multi-agent system (CMAS). As a CMAS, agents of the system could be from various originations and have various expertises, knowledge and capabilities. This makes it hard to describe agents' knowledge clearly in a particular formal way. Agents of a CMAS are experts in some particular area(s). They not only possess special knowledge but also expertise and experience to solve some particular problems. Take medical diagnosis as an example, various human experts or/and diagnose-agents from different branches are grouped together to give proper diagnosis for patients. Each agent has its own knowledge, experience and expertise of own branch

area. However, some of their knowledge (especially for human experts) is hard to be formally described or even discovered. Through several preliminary knowledge mining steps, it is impossible to find out and describe all knowledge of every agent in the system. Furthermore, some kinds of information, such as experience, even might not be well realized by the agent itself.

Definition 1: *An expert* is a major member (either software agent or human expert) in a complex multi-agent, with the knowledge of the agent world and the expertise for a particular problem solving in a special field.

Definition 2: *Knowledge of an expert* can be classified as domain knowledge (understanding of the agent world) and special knowledge (expertise).

Comparing with common agents, an expert is more sophistic. It has ability to check, modify and update knowledge according to its own expertise and experience. It has strong learning ability to improve its capability (accumulate experience). On the other hand, experts also bring dynamics to the system. As an expert improves its knowledge and ability, the overall capability and domain knowledge of the system should also be modified (see Fig. 1).

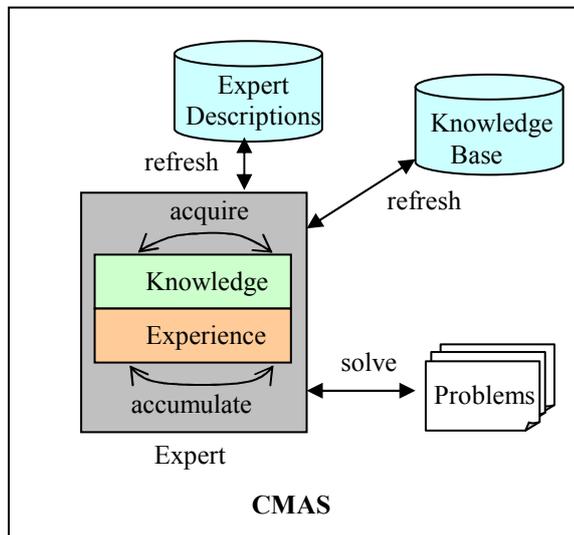

Fig. 1. Expert in a CMAS

For a CMAS, expert discovery is another important process. This process is to estimate expertise of experts, category experts into proper areas and find out suitable experts for incoming tasks.

In this research, we use ontology to describe knowledge of agents, experts, and domain knowledge of complex systems. Ontologies are formal knowledge specifications that can be understood by agents. In our research, we take OIL languages as the ontology specification language. OIL [21] is an advanced ontology language that has rich representation formalism and ontological modelling primitives. An ontology in OIL is represented via a set of ontology definitions. Four key words, which are *class-def*, *subclass-of*, *slot-def*, and *slot-constraint*, are used in ontology definitions to describe relationships of different concepts. The meanings of these four key words are described as follows:

- class-def: a class definition associated with a class name and a class description;
- subclass-of: a statement of a class's parent class(es);
- slot-def: a slot definition associated with a slot name; and
- slot-constraint: a list of global constraint(s) applied to a slot (a slot can also be called as a role or an attribute).

3   Ontology

To facilitate knowledge and expert discovery in CMASs, in this research, we establish ontology to describe conceptually concise basis of system knowledge.

3.1   Ontology in MASs

In the area of MASs, an ontology is a description of the concepts, relationships and constraints that can exist for an agent/expert or a community of agents/experts [2, 11, 19]. It can provide not only a description for knowledge contents but also relationships between different knowledge. Ontologies in MASs normally specify conceptualization of a domain in terms of concepts. Each concept represents a class for a specific set of entities. In an ontology, the concepts are typically organized into a taxonomy tree, and each node of the tree represents a concept. Concepts are linked together by means of their semantic relationships. In Fig. 2, we give a simple example of ontology that describes "University Department". In this example, nodes represent concepts of

the domain and arrows show the relationships between these concepts.

Fig. 2. Example of Ontology

Ontologies of a MAS can be classified as common ontology and special ontology. Common ontology is used to describe domain knowledge of the system. It is written in a formal language which can be understood by all agents of the system. Especially in CMAS, some sophistic agents (experts) may have unshared ontology for its specialized area. This kind of ontology is defined as special ontology. A special ontology is not published in the system and could be written in some specific format that only can be understood by the expert. An expert can also publish its special ontology to the system. However, the special ontology must be translated into the common language and map into common ontology of the system before it is published. This process can be executed by facilitate agents of the system (see Fig. 3). The formally definitions of these two types of ontologies are defined by Definition 3 and Definition 4, respectively.

Definition 3: A *common ontology* is a description of common knowledge that is related to a MAS's working domain or the multi-agent society. Common ontologies are reachable for all agents of a MAS.

Definition 4: A *special ontology* is a description of some specific knowledge that is related to some particular agents or a single agent of a MAS. A *special ontology* is generated by an individual agent from the local view point of the agent. *Special ontologies* are not accessible for all agents of a MAS.

Fig. 3. Common and Special Ontology in a CMAS

3.2 Including Experts in Common Ontology

Experts bring dynamics and difficulties for knowledge discovery in CMASs. On the other hand, they are also the most important part of a CMAS. Whether the knowledge of experts are discovered and applied properly is the key benchmark to evaluate a CMAS. To facilitate exploring experts' knowledge and expertise, in this research, we include experts into the common ontology of the CMAS. Through this way, experts will exist in the common ontology as a class of knowledge and have links with other domain knowledge of the system (see Fig. 4). This brings conveniences for task allocation and knowledge discovery. Through an expert's category and linked knowledge, we can find more effective and pertinent way to achieve expert mining.
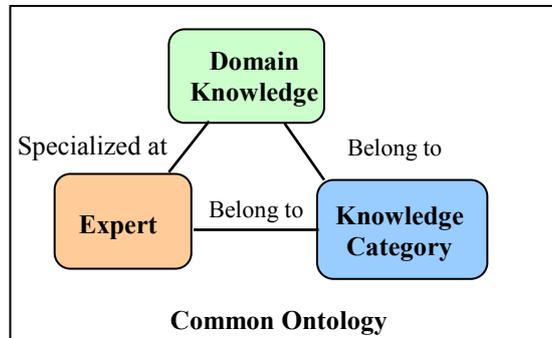

Fig. 4. Including Experts in System Common Ontology

Same as other common ontologies, an expert is also described in a unified/formal format. In this research, we define three compulsory properties for concept expert: specialized area, expertise knowledge and experience value. Fig. 5 shows a simple example of expert ontology that describes a gynecologist. The experience of an expert represents how good the expert is. Experience value must be estimated by a unified rule among the system.

> *Expert name: Dr. Munez;*
> *Specialist Area: gynecologist;*
> *Expertise Knowledge: gynaecology;*
> *Experience: 58;*

Fig. 5. Expert Ontology Example

Ontology provides common understanding knowledge sharing channels between agents and experts and supports expert mining, i.e. to discover suitable team members for problem solving through ontology (knowledge) management. In our knowledge management mechanism, the knowledge and ontology searching services are accomplished by the *Knowledge Searcher* of a MAS. Generally, the *Knowledge Searcher* takes two procedures to process a searching query of an agent, i.e. (1) to search the related knowledge category from the ontology-base; and (2) to retrieve the related knowledge from the knowledge-base. When an agent wants to acquire some domain knowledge, it will send a query to the *Knowledge Searcher*. Receiving a query, the *Knowledge Searcher* searches the ontology-base to obtain related knowledge categories of the query from the *Domain Knowledge Ontology*. Then, the *Knowledge*

Searcher retrieves related knowledge from the knowledge-base according to the knowledge category, which is obtained from the ontology-base. Finally, the *Knowledge Searcher* sends the searching results to the agent.

4 Approach for Knowledge and Expert Discovery

Many current CMAS applications focus on how to extract experts' special rules and convert these rules as system expertise. However, most current CMAS applications have some limitations. Firstly, if knowledge extraction is performed without some particular purpose, it is very hard to say whether the extracted knowledge is useful for the system. Secondly, most of these kind approaches will meet the difficulty to extract knowledge from heterogenous experts. Even if the CMAS can perform knowledge translation between several knowledge representation formats (languages), it is still hard to predict knowledge representation format of the incoming expert especially in an open environment. Finally, most current CMAS applications take expert mining as a one-time process. However, since experts have high learning ability and may work in open environments, knowledge, expertises and experiences of experts are updated frequently. Hence, the (one-time) mining result might be not accurate and complete. Considering these limitations, in this section, we present an ontology-based approach for knowledge and expert discovery in CMASs.

4.1 Expert Estimation and Description

When a new expert joins a CMAS, the fist step to include it into the system is to estimate and describe it in an expert ontology.

There are different ways to estimate machine and human experts. For an agent expert, the estimation is achieved through some data mining or AI methods [9, 14]. Estimating a human expert could be achieved through interviews or surveys. Some CMAS applications take expert estimation is the only step to discover experts' knowledge. However, in this approach, expert estimation is the preliminary step to include a new expect into the system. This process is to draw an overall image of the new expert and find some related knowledge and category for it.

4.2 Task Processing and Ontology Update

In this approach, expert mining is a "life time" process. It will be processed as incoming tasks are solved by experts of the system (see Fig. 6). Here, we assume that all incoming tasks/problems can be described as knowledge format of the system. Then,

the CMAS will be able to map it with the common ontology to the system. The ontology mapping is to put the task in proper categories and explore related knowledge in the ontology. It can have three possible results:

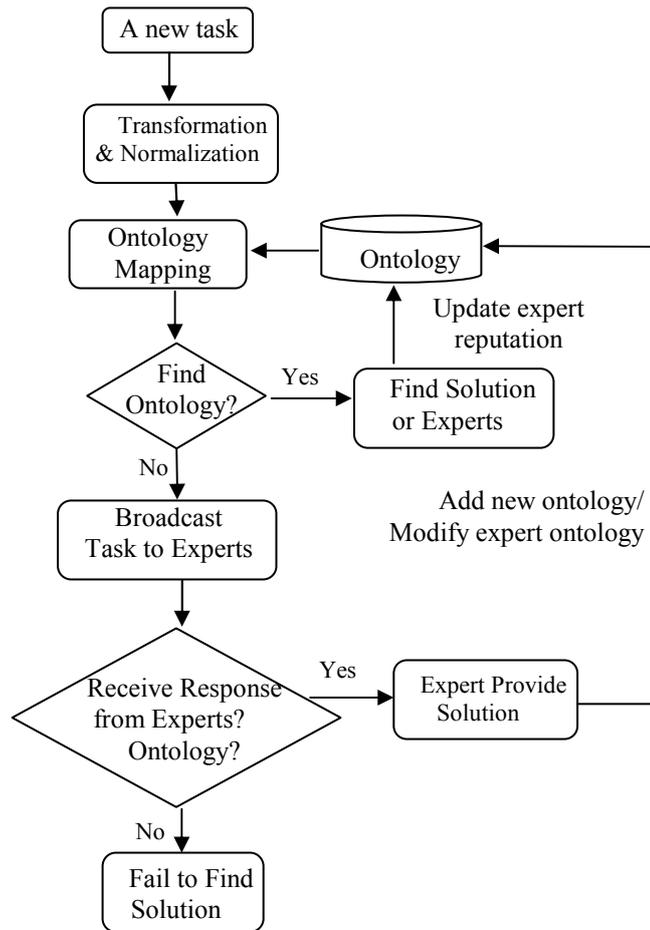

Fig. 6. Ontology-Based Task Processing

a. The task can be mapped and the solution for the task can be found in the current common ontology. In this case, the incoming task might be achieved in the system before, and current common ontology is sufficient to provide solution. The common ontology and knowledge will not be refreshed.

b. The task can be mapped but the solution cannot be found in the current common ontology. Normally, this situation occurs when same kind of tasks

has been solved in the CMAS, but the task is different with previous (solved) tasks. Another possibility is that experts in the system have solved this kind of problems before, but they did not publish their solutions in the system. In this case, the CMAS will allocate experts that are in the same category of the task to solve the task. After the task has been solved, the system will modify the experience value of the expert in the common ontology.

c. The task cannot be mapped in current common ontology, which means the task has never been done by the system, and there is no suitable category can be found. In this case, the system will broadcast the task description to all experts of the system and see whether there exist any experts who can solve this task. If no expert gives response, the task will be rejected by the system. If there is an expert who can do the task, the system will allocate the task to it. After the task is solved, the system will set up links between the task and the expert in the common ontology. Also, the expert can publish its expertise and knowledge in the system.

4.3 Experts' Experience

In a CMAS, there may have more than one experts in the same area. These experts may have conflicts on their special knowledge, expertises and solutions. In this case, the system will choose the expert with higher experience value. The experience value can be considered as the reputation of experts. It is calculated according to the previous task execution result of the expert. An expert's experience value could be increased or decreased depending on the performance of a task.

Another case that the system may need to estimate the reputation of an expert is when the expert wants to refresh the common knowledge of the system. In this case, the system needs to evaluate whether the expert is specialized in that area through estimating its experience value. If the value is greater than the specialist threshold, the system will allow it to publish the knowledge. If the value is medium, the system will find out other experts in the area and collect suggestion from them. The knowledge refresh request will be rejected if its experience value is too low.

4.4 Example

In this subsection, we give a simple example to illustrate the expert mining processes

in this approach. Suppose that there is a CMAS with four experts, i.e. *ExpA, ExpB ExpC* and *ExpD*. Expert ontologies of the four experts are shown in Fig. 7. From Fig. 7, it can be seen that the specialist areas of *ExpA, ExpB, ExpC* and *ExpD* are gyne-cologist, paediatrician, gynecologist and neurologist, respectively. We also suppose that there are two new tasks *tA* and *tB* come into the CMAS. The required knowledge and expertise area of *tA* is gynaecology, but the required knowledge and expertise area *tB* is unknown.

Since the specialist area of *ExpA* and *ExpC* is matched with *tA*, *ExpA* and *ExpC* are potential experts to solve *tA*. According to the experience value of *ExpA* and *ExpB* (See Fig. 7), *ExpA* has a higher experience than *ExpC*. Hence, *ExpA* is selected to handle *tA*. Then, if *tA* is solved by *ExpA* successfully, the experience value of *ExpA* will be increased. Otherwise, the experience value of *ExpA* will be decreased.

Since the required knowledge area of *tB* is unknown, we cannot find a suitable ex-pert to solve *tB* directly. In this situation, *tB* will be broadcasted to all experts of the system. Then, all experts of the CMAS will evaluate whether they can solve *tB*, and give response to indicate whether they can accept it. Here we suppose that only *ExpB* give a positive response to accept *tB*. In this case, *tB* will be allocated to *ExpB*. After *ExpB* solves *tB*, the expert ontology of *ExpB* will be modified and *tB* will be added to its specialist area with an initial experience value (i.e. experience = 1).

Expert name: ExpA; *Specialist Area: gynecologist;* *Expertise Knowledge: gynaecology;* *Experience: 58;*	*Expert name: ExpB;* *Specialist Area: paediatrician;* *Expertise Knowledge: pedology;* *Experience: 60;*
Expert name: ExpC; *Specialist Area: gynecologist;* *Expertise Knowledge: gynaecology;* *Experience: 56;*	*Expert name: ExpD;* *Specialist Area: neurologist;* *Expertise Knowledge: neurology;* *Experience: 43;*

Fig. 7. Ontology-Based Task Processing

From this example, it can be seen that by using expert ontologies to describe ex-perts of a CMAS, we can easily find suitable experts to handle incoming tasks. With an incoming task, we can know the potential experts that can achieve the task, accord-ing to the Specialist Areas of experts (which are described in expert ontologies). Then, according to the experience values of these experts, we can assign the task to the most suitable expert. In addition, expert ontologies are updated as each task is processed in

a CMAS. This feature makes CMASs more suitable for dynamic working environments. In this approach, the task handling process is also the expert mining process. As processing incoming tasks, unknown knowledge of experts can be discovered.

5   Discussion and Conclusion

A CMAS is a system that contains hybrid agents including human agents and autonomous software agents. Agents in a CMAS have strong learning abilities and possess expertises that may be described in different formats. These features bring challenges to knowledge management and discovery in CMASs. Some current CMAS applications hire ontologies to facilitate knowledge management in the system. However, most current CMASs lack of a mechanism to discover expert knowledge and expertise from expert agents. This limitation makes expert agents in a CMAS not been well utilized.

In this paper, we introduce an ontology based approach for expert discovery and knowledge mining in CMASs. This approach uses ontology to manage and structure the domain knowledge of a CMAS and embeds expert ontologies into common ontologies of the system. The contribution of this approach can improve knowledge mining and expert discovery in a CMAS from the following aspects:

1.   The including of expert ontologies brings conveniences for task allocation and knowledge discovery. Through an expert's position in the common ontology, we can find a more effective and pertinent way to achieve expert mining.

2.   In this approach, knowledge mining is a "life time" process that is executed as incoming tasks are solved by experts. Related ontologies of experts of a system will be updated after a task is processed. The "life time" knowledge mining process keeps the descriptions of experts accurate. This improves the adaptability and flexibility of a CMAS in dynamic working environments.

3.   In this approach, "expert experience" is included in expert ontologies. This brings conveniences for handling solution conflicts and can facilitate a CMAS to find suitable experts to execute incoming tasks.

In summary, the ontology-based approach promises more self-learning and self-adjusting abilities to CMASs, and is more suitable for CMASs with high-ability heterogeneous experts and open environments.
